2College of Animal Science, Federal University of Agriculture, Makurdi, Nigeria

Abstract

The carcass characteristics, internal organs and economics of feeding sun-dried cashew pulp based diets to West African Dwarf (WAD) Goats were studied. Twenty growing goats of about 6-7 months, having an average initial weight of 6.42kg were randomly assigned to the treatments; each treatment had five experimental units. Four diets containing 0 (control), 10, 20 and 30% dried yellow cashew pulp coded as T1, T2, T3 and T4, respectively, were compared. Completely randomized design was used in all the experiments. Data obtained were subjected to Analysis of Variance (ANOVA) and means that were significantly different were separated using Least Significant Difference (LSD). None of the carcass and internal organ parameter was significantly affected (P > 0.05) by the inclusion of sun-dried cashew pulp meal. Total feed cost and total variable cost were highly significantly affected (P < 0.01) and feed cost per kg, total feed cost and total variable cost of production reduced as the inclusion level of sun-dried cashew pulp increased from 0% (control) – 30%. This study indicated that sun-dried cashew pulp can be fed to WAD goats up to 30% level of inclusion in diets without an adverse effect on them. Inclusion of cashew pulp sun-dried to the tone of 30% will also provide a cheaper source of feed and also help to reduce environmental pollution since the study area in known to be the highest cashew producing state in Nigeria and the pulp unlike the seed are left to waste during its season.

Keywords

Yellow Cashew Pulp, Carcass Characteristics, Internal Organs and Economics of Feeding

1. Introduction

The major constraint to ruminant animal production in Nigeria apart from the problem of diseases is the shortage of dry season feed, particularly shortages of forage. Grasses which are the most abundant basal feed for ruminants most of the times dry up and become low in nutritive value thereby leading to a marked decrease in voluntary intake and digestibility [1]. Also livestock farmers in developing countries are faced with various challenges that lead to considerable fall in the production of certain livestock species like goats, cattle, swine and poultry, which further leads to protein shortage. This is due to the high cost of production that originates from increase in prices of conventional feed ingredients and livestock species.

According to [2], protein intake in North America, Western and Eastern Europe has been put at 66 g, 39 g and 35 g per head per day respectively, while in Africa and indeed Nigeria the figure stands at 11 g per head per day. Regrettably, animal products contribute 15 to 20% of total protein intake of Nigerians [3]. It was further reported that protein from animal sources contribute about 17% of the total

* Corresponding author
E-mail address: ucheleg@yahoo.com (U. Okpanachi)
consumption to the average Nigerian diet compared to a
contribution of about 61% to the total consumption in
Newzealand, 60% in U.K, 71% in the USA and 67% in
Denmark [4].

Goats, like cattle, have played an important role in the
livelihood of rural people in Africa. Indigenous goats are
more common than the improved goats. These local goat
breeds constitute valuable sources of genetic material
because of their adaptation to harsh climatic conditions, their
ability to better utilize the limited and poor quality feed
resources and their resistance to a range of diseases such as
internal parasites and others. They also supply precious
proteins of high biological value in the form of milk, and
meat. The 2001 population of livestock in Nigeria has been
estimated to be 45.26 m goats, 118.59 m poultry, 28.69 m
sheep, 15.60 m cattle, 5.25 m pigs and 1 m horses, camels
and donkeys [5]. This is against an estimation of 34.5 million
goats, 170 million poultry, 22.1 million sheep, 14 million
cattle and 3.4 million pigs [6]."

In Nigeria, goats and sheep contribute about 30% of the total
meat consumption [7]. The goats in Nigeria represent an
important source of meat and the demand for goat meat is
very high especially in rural areas where it often commands
higher market price than beef [7]. Nevertheless, goat
production is severely limited by inadequate nutrition
especially during the dry season where there is a decline in
the yield and quality of forages [7].

Cashew pulp is considered as a waste in cashew nut
processing industry. Although there is growing awareness
surrounding the economic importance of cashew production
in Asian and African countries, the present practice in most
established large-scale plantations is to allow the apples to
fall from the trees naturally before harvesting the nuts. This
contributes a gross waste of this versatile cashew product [8].
[9] also corroborated the manner in which cashew apple pulp
has been underutilized, and therefore suggested the
development of a new product to minimize the pulp waste by
fermenting the juice, yielding an alcoholic beverage such as
wine. The pulp of cashew apple is very juicy, but the skin is
fragile. When these fruits are dried, they turn brown due to
effect of heat on them and these can be incorporated in feed
to be fed to animals such as cattle and goats. It is rich in
Vitamin C than oranges and contains high amount of mineral
salts ([10]; [11]).

The utilization of abundant cashew pulp in cashew growing
areas like Kogi State, Benue State etc, will help to reduce the
waste that characterizes cashew production season. According
to personal interview with the staff of Cocoa
Research Institute of Nigeria (who has cashew as one of their
mandate crops), Kogi state is the highest cashew producing

The sample of yellow cashew apple pulp was obtained from
Anyigba and its environs. Anyigba is in Kogi State, Nigeria.
They were washed, sliced with the aid of knives and
chopping boards into bits, air-dried and moved to the glass
house where they were properly dried. The dried cashew pulp
were packaged, weighed and stored in a safe place. The dried
cashew pulp was later milled.

2.2. Location of the Study

This study was carried out in the Sheep and Goat Unit of the
Teaching and Research farm of Kogi State University,
Anyigba. Anyigba is located on longitude 07°30’ N and
latitude 07°09’ E [12]. The study area falls within the tropical
wet and dry climatic region and the guinea savanna belt of
Nigeria. The mean annual rainfall and temperature of 1250
mm and 25°C respectively [13].

2.3. Experimental Procedure, Management
and Duration of Study

A total of twenty male West African Dwarf goats of about 6-
7 months, having an average initial weight of 6.42 kg were
obtained from goat producers within Anyigba town for this
experiment. Goats were housed in wooden cages in the pens.
Each cage measured (100 x 85 x 60) cm and the cages were
built on wooden stands, 40 cm from the floor. Before the
goats were brought in, the pens were cleaned, washed and
disinfected with detol and izal solution. The entire goat
house was fumigated using strong fumigants (Dimethoate
40% and Action 40%) against fleas. Prophylactic treatments

were given to all the goats: they were dewormed using Albendazole oral and ivermectin (vetometh), and also vaccinated against PPR using PPR vaccine, subcutaneously. Iron injection (iron dextrin) was administered and Ivax was also administered orally to combat diarrhoea, tylosan intramuscularly to fight against cold and catarrh. Treatment against ecto-parasites was done with the use of Amixtraz solution. Multivitamin was also administered to boost appetite. Antibiotics such as oxytetracycline (long acting) were administered. The goats were randomly distributed to 4 groups of 5 animals each. Each goat served as a replicate. An adjustment period was allowed for the goats before data collection commenced. Goats were fed daily between the hours of 8:30 am and 9:30 am based on 5% body weight. Left over feeds and water were weighed and measured daily to facilitate calculation of feed and water intake. Weighing of the goats was done weekly to determine the weight and feed conversion ratio. The experiment commenced in the month of August and lasted for a period of 107 days.

2.4. Carcass and Internal Organ Parameters

At the end of the experiment, two (2) goats per treatment, and a total of eight (8) goats were used for carcass evaluation. The selected goats were fasted for 24 hours prior to slaughter, providing them with only water, after which they were weighed to obtain live weight, and slaughtered. The slaughtered goats were roasted, internal organs removed and weighed to get the carcass weight (head, legs, kidneys, heart and liver were left on the carcass and considered as carcass weight). Dressing percentage was calculated by working the percentage of the ratio of the weight of carcass to the live weight. Internal organs were weighed using the electronic weighing scale in order to obtain more accurate values. The followings were evaluated:

(i) Live weight
(ii) Carcass weight
(iii) Dressing percentage (%)
(iv) The following parts were weighed: head, neck, thigh, legs, heart, lungs, liver, kidney, spleen, testes, full gut and empty gut.

All these parts were calculated as percentage live weight.

2.5. Determination of the Economics of Feeding Sun-Dried Cashew Pulp Based Diet to West African Dwarf Goats

The economics of feeding dried cashew pulp based diet to West African Dwarf goats were calculated and determined using some basic formulae as shown below:

Total Variable Cost of Production = Cost of Goat + Cost of other variable inputs

Gross Margin = Selling Price (Revenue) – Total Variable Cost of Production

Cost Benefit Ratio = Revenue

Total Variable Cost of Production

Total Feed Cost = Total Feed Intake × Cost of Feed/kg.

Feed Cost per Kg Gain = Feed Conversion Ratio × Feed Cost.

2.6. Effect of Feeding Sun-Dried Cashew Pulp Based Diets on Carcass Characteristics and Internal organs of Experimental Goats

The effect of feeding sun-dried cashew pulp based diets on carcass characteristics of experimental goats is presented in Table 2. None of the carcass parameter was significantly affected (P > 0.05) by the inclusion of sun-dried cashew pulp meal. Live weight ranged from 7590.00 (T1) – 8325.00 (T3); Carcass weight ranged from 4360.00 (T1) – 4755.00 (T2); dressing percentage ranged from 55.99 (T1) – 57.66 (T3); head ranged from 7.40 (T2) – 8.06 (T3); neck ranged from 3.37 (T1) – 4.03 (T2); thighs ranged from 17.65 (T3) – 19.34 (T1); legs ranged from 2.38 (T2) – 2.84 (T3); heart 0.53 (T2 and T3) – 0.59 (T1); lungs ranged from 1.22 (T2) – 1.41 (T1); liver ranged from 1.99 (T3) – 2.37 (T2); kidneys ranged from 0.38 (T1 and T2) – 0.41; spleen ranged from 0.15 (T3) – 0.19 (T1); testes ranged from 1.00 (T1) – 1.49 (T2); full gut ranged from 28.18 (T2) – 34.38 (T3) and empty gut ranged from 8.99 (T1) – 9.33 (T3).

2.7. Effect of Feeding Sun-Dried Cashew Pulp Based Diets on Economics of Production of Goats

The effect of feeding sun-dried cashew pulp based diets on economics of production of goats is presented in Table 3. Total feed cost and total variable cost were highly significantly affected (P < 0.01) by the inclusion of sun-dried cashew pulp meal. All other parameters under the economics of feeding sun-dried cashew pulp to goats were not significantly affected (P > 0.05). Values for feed cost per kg ranged from 11.05 (T4) – 18.06 (T1); feed cost per kg gain values ranged from 338.79 (T4) – 948.56 (T3); protein efficiency ratio ranged from 0.01 (T4) – 0.27 (T2); energy efficiency ratio ranged from 0.001 (T2, T3, T4) – 0.009 (T4); total feed cost ranged from 247.23 (T4) – 426.40 (T1); total variable cost of production ranged from 4956.40 (T4) – 5135.60 (T1); gross margin ranged from 894.74 (T3) – 1046.70 (T2) and cost benefit ratio ranged from 1.180 (T3) – 1.210 (T4).

3. Discussion

3.1. Effect of Feeding Sun-Dried Cashew Pulp Based Diets on Carcass Characteristics and Internal Organs of Experimental Goats

None of the carcass and internal organ parameters was affected by the inclusion of sun-dried cashew pulp meal. The cashew apple meal inclusion in animal diets did not influence dressing percentage, weight of spleen, gizzard, and heart but there was a significant reduction in liver size (P < 0.05) [14]. Dressing percentage in this study ranged from 55.99% – 57.66%. The dressing percentage in this study is higher than 43.80% – 47.30% reported by [15] who fed cassava meal-based diets to WAD goats. [16] reported dressing percentages of 39.99%, 41.17% and 45.41% for Balaami, Uda and Yankassa sheep respectively. These dressing percentages are lower than the result obtained in this study. [17] who studied the carcass and non-carcass components of male WAD goats slaughtered at different weights (10 –20 kg) reported a dressing percentage of 40.02% - 56.88% (P < 0.05) which is close to that obtained in this study. The variations in dressing percentages across the various studies cited might be due to difference in slaughter technique, breed, nutrition [18], and body weight (both initial and final). This goes in line with the contributions of [19], who reported that dressing percentage, can be influenced by many factors such as fleece and hide weight, alimentary tract size and fill, slaughtering procedure and partitioning of body fat. Also the dressing method can affect the dressing percentage because, parts which are considered offals may not be considered offal in some dressing methods. An example is that of [18] who consider hot carcass weight to be carcass weight – legs + head, and normal carcass weight as Empty body weight – Gastro- intestinal tract (GIT). By so doing, calculation of dressing percentage as recommended by [18] will give a rather higher value when compared to [15] who reported warm carcass to exclude all internal organs, the skin, the head, the feet as well as viscera and abdominal fat. Age, nutrition, sex, pre-slaughter weight, gut fill and slaughter by-products are some of the factors that affect carcass characteristics [20]. Carcass weight in this study ranged from 4360.00 g in T1 – 4755.00 g in T4. This could mean that goats on sun-dried cashew apple pulp-based diet better utilised feed for meat production, particularly goat under T2. This can be further explained by the higher neck weight for goats on diets containing sun-dried cashew pulp meal when compared to those on the control diet. The weight of the head, neck thighs, legs, heart, lungs, liver, kidneys, spleen, testes, full gut and...
empty gut in this study were all expressed as percentage live weight. They were not affected by the inclusion of sun-dried cashew pulp meal. The decrease in the weight of the head as the carcass weight increased agrees with the study by [17]. Internal organs such as the liver would vary by enlargement if the diets contained poisonous substances. The non-significance in the internal organs could mean that the test diet is safe for the animal’s consumption. Heart weight in this study was almost similar for all the treatments. This is a good sign since abnormal blood circulation would cause variation in the size of the heart [21]. Non-significance between the values for heart is an indication that blood circulation of goats placed in all the treatment was normal. This also shows that the kidneys (excretory organ) were not over burdened by the inclusion of sun-dried cashew pulp meal in the dietary treatments, thus its excretory function was not impaired [22].

3.2. Effect of Feeding Sun-Dried Cashew Pulp Based Diets on Economics of Production of Goats

The effect of feeding sun-dried cashew pulp based diets on economics of production of goats shows that total feed cost and total variable cost were highly affected by the inclusion of sun-dried cashew pulp meal. All other parameters were not affected. Values for feed cost per kg in this study ranged from N11.05 in T₄ – N18.06 in T₁ and this is lower than N16.00 - N36.00 reported by [23] who fed crop by-products (peels of yam, cassava, sweet potato and ripe plantain) to West African Dwarf bucks. The feed cost per kg in this study is this low, considering the fact that the feed was completely made up of non-conventional feed stuffs. The feed cost per kg obtained in this study shows that the feed cost per kg reduced from T₁ to T₄ as the inclusion of cashew pulp increased from 0% in T₁ to 30% in T₄. Feed cost per kg gain in this study ranged from 338.79 in T₄ – 948.56 in T₁. This is higher than N169.17 – 214.30 reported by [23]. The very high feed cost per kg gain (948.56) obtained for T₁ in this study is as a result of a decrease in body weight gain of the experimental WAD goats which led to a very high FCR in T₁ since feed cost per kg gain is the product of FCR (ratio of the total feed consumed in grammes and total weight gain in grammes per treatment) and feed cost per kg. Slight decrease was observed for most of the treatments, with goats in T₃ having the major decrease in body weight gain. The general decrease in body weight gain may be due to the health challenges faced by the goats as a result of the season (rainy season), with those in T₃ having the worst hit. The total feed cost for T₁ was higher than for other treatments. The total variable cost of production for T₁ was higher than for other treatments. Total variable cost of production in this study ranged from N4956.40 in T₄ - N5135.60 in T₁ and it is a true indication of the effect of the feed cost in the overall goat production as reflected in the total cost of feed consumed in which T₁ had the highest value while T₄ had the least. Gross margin in this study ranged from N894.74 (T₃) – N1046.70 (T₂) and this shows that more profit can be generated by farmers with increased level of sun-dried cashew pulp meal inclusion in goat diets. Cost benefit ratio ranged from 1.180 (T₃) – 1.210 (T₄), which means that farmers can acquire more benefits and less cost from the use of sun-dried cashew pulp as a feed stuff in livestock feed.

4. Conclusion and Recommendations

Studies on carcass characteristics, internal organs and economics of feeding sun-dried yellow cashew pulp based diets to West African Dwarf Goats showed that yellow cashew pulp sun-dried at 30% inclusion had no adverse effect on carcass characteristic, internal organs and economics of production. This is supported by the fact that none of the carcass and internal organ parameters was affected by the inclusion of sun-dried cashew pulp meal (p > 0.05). Feed cost per kg, total feed cost and total variable cost of production reduced as the inclusion level of sun-dried cashew pulp increased from 0% (control) – 30%.
